1 Part 1 Algorithm

1.1 Asymptotic run-time analysis

My algorithm runs in asymptotic time $O(log(n)$. The argument for this follows:
My algorithm has three parts:

1. load data into array
2. sort array
3. find 90́th percentile value

The loading of the data from file $O(n)$.
Sorting the array with stdlib quicksort $O(n * log(n))$.
Finding the 90́th percentile value $O(1)$.
this suggests that the dominating factor is the quicksort.

1.2 Experiments

The description of the experiments goes here:
I tested the algorithm with increasing number of n from 1 to $10,000,000$ in powers of 10.

1.3 Prediction

My estimate of the equation for the run-time of the algorithm is:

$$t(N) = 2.4 \times 10^{-8} * log(n) \tag{1}$$

Using this, the estimated time to find the ninetieth percentile of a file containing 60 million numbers is 25.79 seconds.

2 Part 2 Algorithm

2.1 Asymptotic run-time analysis

My algorithm runs in asymptotic time $O(XXXX)$.
The argument for this follows: XXXX

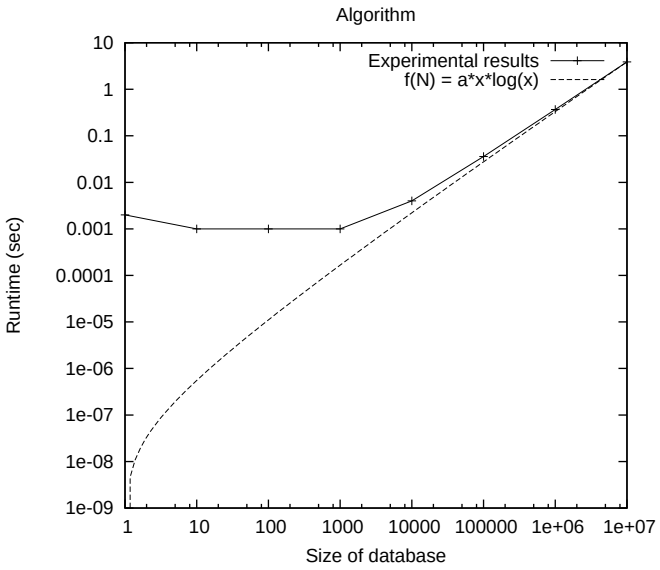

Figure 1: Real time vs count of numbers

2.2 Experiments

The description of the experiments goes here: XXXX

2.3 Prediction

My estimate of the equation for the run-time of the algorithm is:

$$t(N) = XXXX \tag{2}$$

Using this, the estimated time to find the ninetieth percentile of a file containing 60 million numbers is XXXX seconds.
